These observations allow us to relate local deposition rates in various regions of the composite to the connectivity of the surrounding network of porosity and to better model the relationship between gas transport and fiber architecture in CVI preforms. Simulation results agreed with the experiments for what concerns the general shape and the location of secondary flows. The oxyacetylene torch testing and three point bend testing have been performed on test panels and the test results are presented. In this paper, for the first time in literature, a stochastic approach is proposed to include these variations in LES.

Designed for readers who need to understand and apply the engineering physics of ceramics culture was sophisticated and well developed.
